APE-GAN: adversarial perturbation elimination with GAN

The essence of the model is to eliminate the adversarial perturbations in the samples. The model use the adversarial samples themselves to generate corresponding real samples.

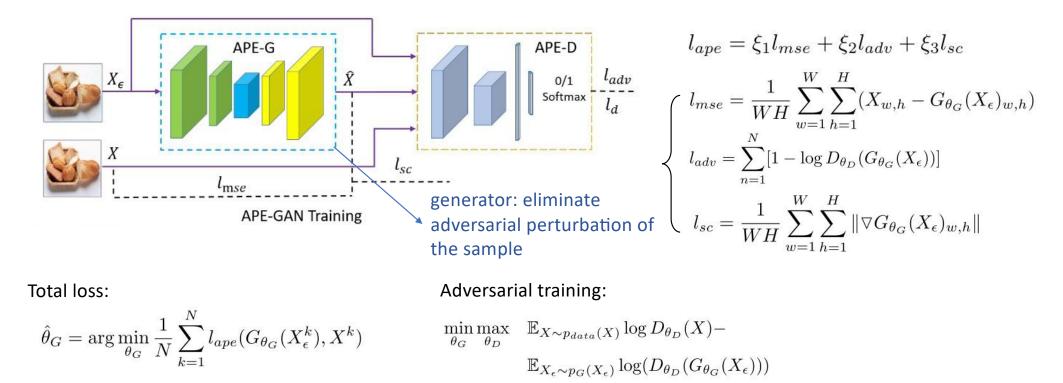

• WHITE-BOX ATTACK MODELS

- White-box models assume that the attacker has complete knowledge of all the classifier parameters, i.e., network architecture and weights, as well as the details of any defense mechanism
- targeted attack: they attempt to cause the perturbed image to be misclassified to a specific target class
- untargeted attack: when no target class is specified
- BLACK-BOX ATTACK MODELS
 - black-box adversaries have no access to the classifier or defense parameters, It is further assumed that they do not have access to a large training dataset but can query the targeted DNN as a black-box.

Defense-Gan: Protecting classifiers against adversarial attacks using generative models

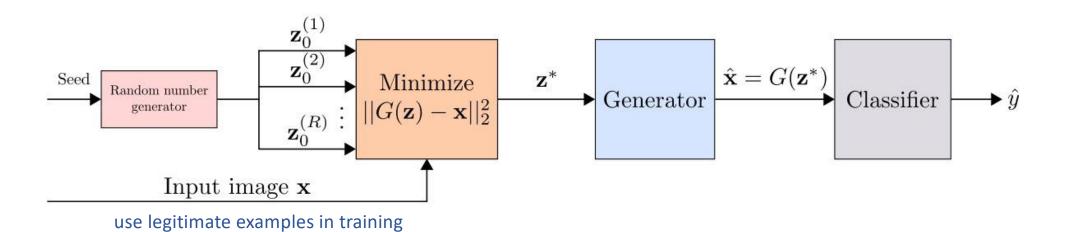

APE-GAN: adversarial perturbation elimination with GAN

14

• Defense-GAN

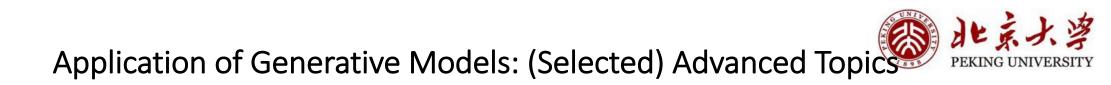

• a new defense strategy which uses a WGAN trained on legitimate (un-perturbed) training samples to "denoise" adversarial examples.

Defense-Gan: Protecting classifiers against adversarial attacks using generative models

- APE-GAN:
 - Use **adversarial samples** as the input of the generator.
- Defense-GAN:
 - Use multiple random noise as the input of the generator.
 - Implement adversarial training without using adversarial samples as inputs.
- Both of the structures are based on WGAN.

Meta Learning

Definition

- In the context of machine learning, meta learning is the process of **learning to learn**.
- Informally speaking, a meta learning algorithm uses experience to change certain aspects of a learning algorithm, or the learning method itself, such that the modified learner is better than the original learner at learning from additional experience.

Meta Learning

Meta Learning Architecture for few-shot learning with generative models ٠

from training set unseen frame

 $Target \rightarrow Landmarks \rightarrow Result$ Source Source **Target** \rightarrow **Landmarks** \rightarrow **Result**

In fact, this system can generate a reasonable result based on a single photograph (one-shot learning), while adding a few more photographs increases the fidelity of personalization

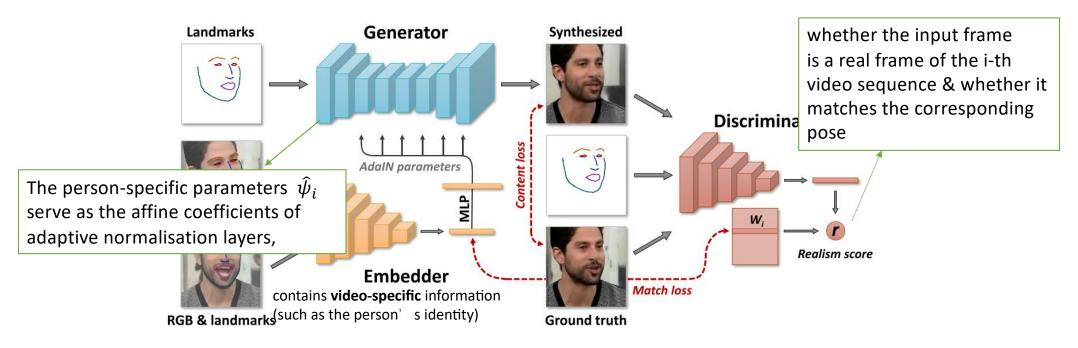

Meta Learning

• Meta Learning Architecture for few-shot learning with generative models

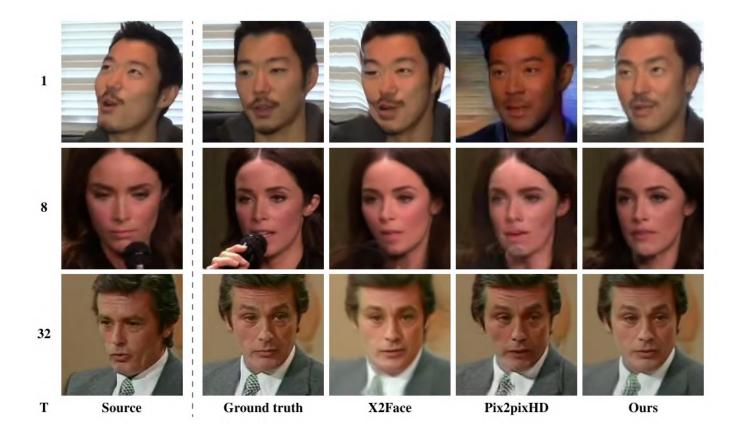

- All parameters of the generator are split into two sets: person-generic parameters ψ , and the person-specific parameters $\hat{\psi}_i$.
- During meta-learning, ψ are trained directly, while $\hat{\psi}_i$ are predicted from the embedding vector \hat{e}_i using a trainable projection matrix **P**: $\hat{\psi}_i = \mathbf{P}\hat{e}_i$

Reinforcement Learning

• World Models

One way of understanding the predictive model inside of our brains is that it might not be about just predicting the future in general, but predicting future sensory data given our **current motor actions**

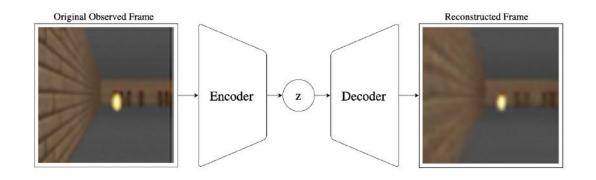

Learning in the imagination == Sampling efficiency

Reinforcement Learning

World Models

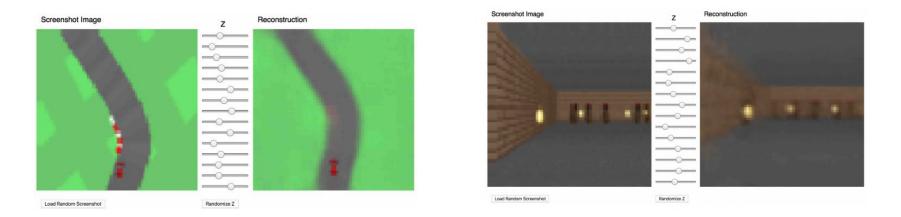

Learn the state representation

Here .. The encoder output is the state

Reinforcement Learning

World Models

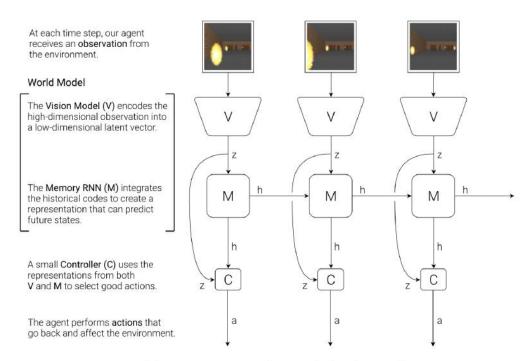

In this model, the agent has a visual sensory component that compresses what it sees into a small representative code.

Ha D, Schmidhuber J. World models[J]. arXiv preprint arXiv:1803.10122, 2018.

Reinforcement Learning

World Models

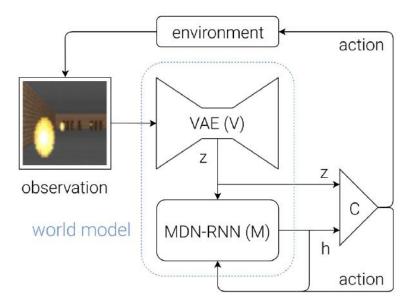

Our agent consists of three components that work closely together: Vision (V), Memory (M), and Controller (C).
